January 23-25 Dip

Jan 23-25: Extreme cold + major snowstorm
Wind chills hit -36°F (Jan 23), followed by a snowstorm dropping 2-10" of snow (Jan 24-25). Rides fell ~85% below baseline. City opened emergency warming centers. Ridership recovered within 24 hours of the storm clearing.

Divvy Bike Share — January 2026 Performance Summary

Casual Share 6-9am (vs. Member Rides)

13%

Casual Share Overnight (vs. Member Rides)

39%

Members commute, casual riders don't

Member rides show a clear 8am/5pm double-peak—a textbook commute pattern. Casual riders show no morning spike at all: only 13% of 6-9am rides are casual, vs. 39% overnight. Casual usage skews toward leisure and off-peak trips, not commuting.

Riders' Bike Preference

Divvy Bike Share — January 2026 Performance Summary

16.33

Classic Avg Duration (Minutes)

9.69

Electric Avg Duration (Minutes)

Electric bikes get shorter, faster trips

Classic bike rides average 16.3 min vs. 9.7 min for electric — a ~70% difference. Electric bikes also dominate overnight hours by a wider margin (2.5-3x) than during the day (~2x), echoing the same casual-rider pattern seen in Member vs Casual: casual riders lean electric and ride more overnight.

Divvy Bike Share — January 2026 Performance Summary

Rides by Day of Week

DayName	Total Rides	Days Covered	Avg Rides Per Day
Sun	11,901	4	2,975.25
Mon	18,557	4	4,639.25
Tue	26,295	4	6,573.75
Wed	23,255	4	5,813.75
Thu	23,038	5	4,607.60
Fri	19,931	5	3,986.20
Sat	14,787	5	2,957.40
Total	137,764	31	4,444.00

The cold snap's effect outlasted the storm itself

Daily rides recovered quickly after Jan 25, but the 7-day trend line kept declining through Jan 27-29 — the extreme low days were still being averaged in even after conditions improved. The smoothed trend only shows full recovery by early February.

Daily Rides - Raw vs. 7-Day Trend

Divvy Bike Share — January 2026 Performance Summary

Most rides are short — and "outlier" doesn't mean "broken"

68% of rides last under 10 minutes. Statistically, anything over 23 min counts as an outlier (IQR method) — but that's 7.15% of all rides, mostly real trips, not bad data. True broken/lost-bike cases cluster near 24 hours; a review of the 120+ min bucket (842 rides) shows a mean of 671 min with a 75th percentile of ~21 hours — suggesting some "forgotten bike" cases may be hiding well below our original 24-hour DQ cutoff.

Usage is broad-based, not concentrated in a few hotspots

1,139 unique stations serve January's riders. The top 10 stations account for just 8.3% of rides — it takes roughly 130-150 stations (about 13% of the network) to reach half of all ridership. Unlike systems with a few dominant hubs, Divvy's usage is spread across the whole city — no single station is a point of failure for the network.

Trip Duration Distribution

Station Usage Concentration

Divvy Bike Share — January 2026 Performance Summary

Three station personas emerge from usage patterns

Using simple threshold rules (commute-hour %, member %, electric-bike %), January's 359 active stations split into: **Commuter Hubs** (101 stations, led by Canal St & Madison St) — high commute-hour and member share; **Leisure Hubs** (87 stations, incl. Wilton Ave & Belmont Ave) — high electric-bike share, more casual riders; and **Mixed Use** (171 stations, incl. the Hyde Park/University cluster) — no dominant pattern. Note: since 3 variables define the segments but only 2 are plotted here, some overlap between colors is expected — a true multi-dimensional clustering method (e.g. K-means) would separate these more precisely.

Station Segments: Commute % vs Electric %

Segment ● Commuter Hub ● Leisure Hub ● Mixed Use

Divvy Bike Share — January 2026 Performance Summary

Electric bikes: predictable pace. Classic bikes: variable effort.

Average duration rises with distance for both bike types, but classic bikes climb more steeply (81 min at 10+ km vs. 42 min for electric) — slower average pace *and* far more ride-to-ride variability ($r = 0.11$ vs. $r = 0.48$). Electric bikes' motor assistance likely produces more consistent speeds regardless of rider effort, making individual-ride duration more predictable from distance alone.

Weather is the strongest driver of ridership found in this entire analysis

Daily average temperature and total rides correlate strongly ($r = 0.864$) across all of January — far stronger than any other relationship examined in this project. This confirms and quantifies what Pattern 3 first uncovered qualitatively: the Jan 23-25 cold snap and snowstorm weren't an isolated anomaly, but part of a consistent, measurable, month-long pattern — colder days reliably mean fewer rides, with real business implications for demand forecasting and bike-rebalancing planning around weather forecasts.
